

# DOM and Events - Part 1

Building Modern Web Applications - VSP2022

Karthik Pattabiraman  
Kumseok Jung  
Mohsen Salehi

# Modern Browsers

1. **Modern Browsers**
2. DOM Event Handling
3. DOM Event Propagation

## Modern Browsers: Browser as an OS

- Modern Browsers are equivalent to an **OS for web applications**
  - Provide core services such as **access to the display** (DOM, location bar), and **permanent state** (cookies, local storage, history)
  - **Schedule event handlers** for different tasks and control the global ordering of events
  - Allow **network messages** to be sent and received from the server

# Modern Browsers: JavaScript Execution Model

- Browser follows two phase execution model

## Phase 1

- All code within the `<script></script>` tag is executed when they're loaded in the order of loading (unless the script tag is `async` or `deferred`)
- Some scripts may choose to defer execution or execute asynchronously. These are executed at the end of phase 1

# Modern Browsers: JavaScript Execution Model

- Browser follows two phase execution model

## Phase 2

- Waits for events to be triggered and executes handlers corresponding to the events in order of event execution (single-threaded model)
- Events can be of four kinds:
  - Load event: After page has finished loading (phase 1)
  - User events: Mouse clicks, mouse moves, form entry
  - Timer events: Timeouts, Interval
  - Networking: Async messages response arrives

## Modern Browsers: window Object

- **Global object** that provides a gateway for almost all features of the web application
- Passed to standalone JS functions, and can be accessed by any function within the webpage
- Example Features
  - DOM: Through the `window.document` property
  - URL bar: Through `window.location` property
  - Navigator: Browser features, user agent etc.

## Modern Browsers: window Object

- **alert**: Simple way to pop-up a dialog box on the current window with an OK button
  - Can display an arbitrary string as message
- **prompt**: Asks the user to enter a string and returns it
- **confirm**: Displays a message and waits for user to click OK or Cancel, and returns a boolean

```
1 do {  
2     var name = prompt("What is your name?");  
3     var correct = confirm("You entered: " + name);  
4 } while (!correct);  
5 // This is bad security practice - don't do this!  
6 alert("Hello " + name);
```

## Modern Browsers: window Object

- `setTimeout` is used to schedule a future event asynchronously once after a specified number of milliseconds (can be set to 0)
  - Can specify arguments to event handler
  - Can be cancelled using the `clearTimeout` method

```
1 var callback = function(){
2     alert("Hello");
3 }
4 var timer = setTimeout(callback, 1000);
5
6 clearTimeout(timer);
```

## Modern Browsers: window Object

- `setTimeout` is used to schedule a future event asynchronously once after a specified number of milliseconds (can be set to 0)
  - Can specify arguments to event handler
  - Can be cancelled using the `clearTimeout` method
- `setInterval` has the same functionality as `setTimeout`, except that the event fires repeatedly until `clearInterval` is invoked

```
1 var count = 0;
2 var callback = function(){
3     alert("Hello " + (count++));
4 }
5 var timer = setInterval(callback, 1000);
6 clearInterval(timer);
```

## Class Activity

[lectures/lecture-5/interval.html](#)  
[lectures/lecture-5/interval.js](#)

- Create a new function that invokes another function `func` a specified number of times `num`, asynchronously, each time after `time` ms
- The function should pass as an argument to `func` the number of times it called `func` so far
  - Hint: You can do it through `setTimeout` or `setInterval`

```
1 function invokeTimes(func, num, time){  
2   // to implement  
3 }  
4  
5 invokeTimes(function(count){  
6   alert("Hello " + count);  
7 }, 10, 1000);
```

# DOM Event Handling

1. Modern Browsers
- 2. DOM Event Handling**
3. DOM Event Propagation

# Event Handling

- JavaScript code is **event-driven**, which means that you need to **register event callbacks**
- Events are of five types in JavaScript
  - Mouse Events (e.g., mouseclick, mousemove, etc)
  - Window Events (load, DOMContentLoaded, etc)
  - Form events (submit, reset, changed etc)
  - Key events (keydown, keyup, keypress etc)
  - DOM events (part of DOM3 specification)

## Event Handling: Cautionary Note

- There are many **browser incompatibilities** regarding the **types of events** implemented, and the way to register event handlers (e.g., IE prior to v9 is different from almost all other browsers)
- This is complicated by the fact that the DOM3 spec itself is a moving target for over 10 years
- In this class, **we will follow DOM2** spec. and assume that the browser is standard-compliant
  - Focus on set of events that are common (except IE)

# Event Handling: Registering Event Handlers

- Two ways of registering event handlers
  - Old method (DOM 1.0): Directly add a `onclick` or `onload` property to the DOM object/window
    - Disadvantage: **Allows only one event handler** to be specified. New handlers must remember to chain the old handler, and can potentially 'swallow' the handler
  - New method (DOM 2.0): Allows multiple event handlers to be added to the DOM object/window

## Registering Event Handlers: DOM 2.0

- The DOM 1.0 method is clunky and can be buggy. Also, difficult to remove event handlers
- DOM 2.0 event handlers
  - `addEventListener` for adding a event handler
  - `removeEventListener` for removing event handlers
  - `stopPropagation` and `stopImmediatePropagation` for stopping the propagation of an event

## DOM 2.0: addEventListener

- Used to add an Event handler to an element. Does NOT overwrite previous handlers
  - Arg1: Event type for which the handler is active
  - Arg2: Function to be invoked when event occurs
  - Arg3: Whether to invoke in the 'capture' phase of event propagation (more later) - false by default

```
1 var elem = document.getElementById("mybutton");
2 elem.addEventListener("click", function(event){
3     this.style.backgroundColor = "#fff";
4     return true;
5 });
```

## DOM 2.0: addEventListener

- Does not overwrite previous handlers, even those set using `onclick`, `onmouseover` etc.
- Can be used to register multiple event handlers – invoked in order of registration (handlers set through DOM 1.0 model have precedence)

```
1 var elem = document.getElementById("mybutton");
2 elem.addEventListener("click", function(event){
3     alert("Hello");
4 });
5 elem.addEventListener("click", function(event){
6     alert("World");
7 });
```

## DOM 2.0: removeEventListener

- Used to remove the event handler set by `addEventListener` functions, with the same arguments
  - No error even if the function was not set as event handler

```
1 var clickHandler = function(event){  
2     alert("Clicked");  
3 };  
4 var elem = document.getElementById("mybutton");  
5 elem.addEventListener("click", clickHandler);  
6 elem.removeEventListener("click", clickHandler);  
7
```

## Event Handler Context

- Invoked in the context of the element in which it is set (**this** is bound to the target)
- Single argument that takes the **event** object as a parameter – different events have different properties, with info about the event itself
- Return value is discarded – not important
- Can access variables in the scope in which it is defined, as any other JS function
  - Can support closures within Event Handlers

## Class Activity: Click Events

[lectures/lecture-5/domclick.html](#)

[lectures/lecture-5/domclick.js](#)

- Consider an HTML containing 3 buttons with ids `reset`, `up`, and `down`
- Write **3 handler functions** for the `click` event of each of the 3 buttons to do the following:
  - `resetBtn` should set the `count` to 0
  - `upBtn` should increment the `count` by 1
  - `downBtn` should decrement the `count` by 1

```
1 window.onload = function(){
2   var count = 0;
3   var resetBtn = document.getElementById("reset");
4   var upBtn = document.getElementById("up");
5   var downBtn = document.getElementById("down");
6   resetBtn.addEventListener("click", /* ??? */);
7   upBtn.addEventListener("click", /* ??? */);
8   downBtn.addEventListener("click", /* ??? */);    };
```

## Class Activity: Closures

[lectures/lecture-5/multiclick.html](#)  
[lectures/lecture-5/multiclick.js](#)

Fix the following code - all buttons are showing the same message!

```
1 function addClickListeners (buttons){
2     for (var i = 0; i < buttons.length; i++){
3         buttons[i].addEventListener("click", function(){
4             alert("Clicked Button " + i);
5         });
6     }
7     return buttons;
8 };
9
10 var btns = document.getElementsByTagName("button");
11 addClickListeners(btns);
12
13
14
```

# DOM Event Handling

1. Modern Browsers
2. DOM Event Handling
3. **DOM Event Propagation**

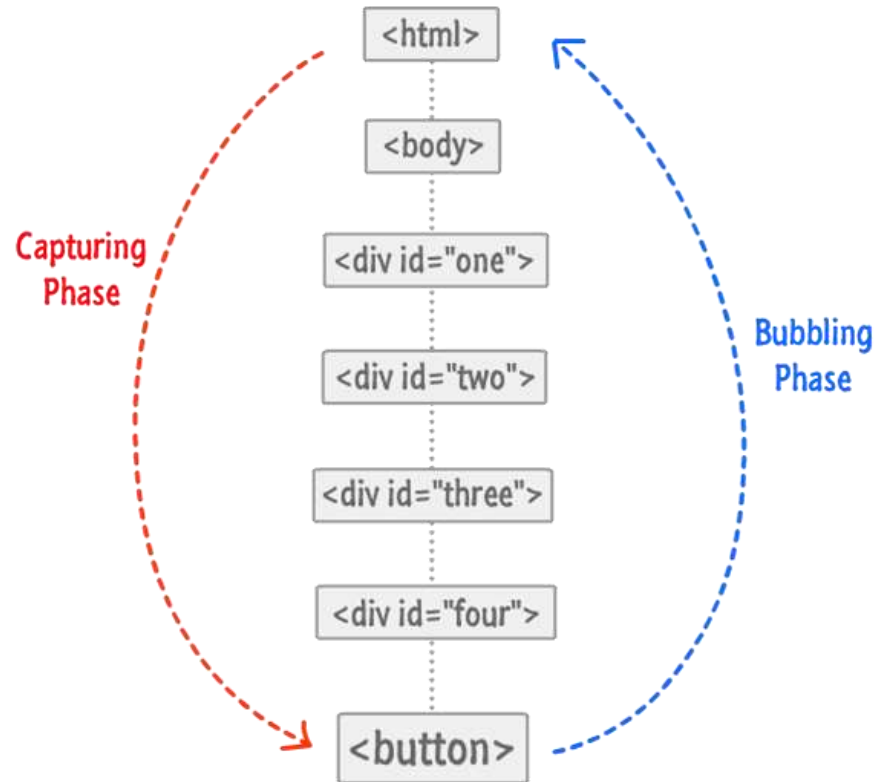

# Event Propagation

- Events triggered on an element propagate through the DOM tree in 2 consecutive phases
  - **Capture phase:** Event is triggered on the topmost element of the DOM and propagates down to the event target element
  - **Bubble phase:** Event starts from the event target element and ‘bubbles up’ the DOM tree to the top
- **Exception:** for the target element itself
  - For the target element itself, the W3C standards considers a **target phase**
  - All handlers registered for the target element are always registered for the target phase – the bubble/capture phase argument is ignored when registering handlers (see later)
  - Events may therefore trigger handlers on elements different from their targets

# Capture and Bubble Phases

## Event Propagation Setup

- To associate an event handler with the capture phase of event propagation, set the third parameter of `addEventListener` to `true`

```
1 var div1 = document.getElementById("one");  
2 div1.addEventListener("click", handler, true);
```

- The default way of triggering event handlers is during the bubble phase (3rd argument is `false`)

# Capture and Bubble Phases

```
1 var div1 = document.getElementById("one");  
2 div1.addEventListener("click", handler1, true);  
3 var div2 = document.getElementById("two");  
4 div2.addEventListener("click", handler2, true);
```

## Capture Phase

- Assume that the `<div>` element `'two'` is clicked.
- `handler1` is invoked before `handler2` as both are registered during the capture phase.

## Bubble Phase

- Assume that the `<div>` element `'two'` is clicked.
- `handler2` is invoked before `handler1` as they are both registered during the bubble phase.

## Stopping Event Propagation

- In the prior example, suppose `handler1` and `handler2` are registered in the capture phase

```
1 var handler = function( clickEvent ){  
2     clickEvent.stopPropagation();  
3 };
```

- Then `handler2` will never be invoked as the event will not be sent to `div2` in the capture phase

## stopPropagation, preventDefault, stopImmediatePropagation

- An event handler can stop the propagation of an event through the capture/bubble phase using the `event.stopPropagation` function
  - Other handlers registered on the element are still invoked however
- To prevent other handlers on the element from being invoked and its propagation, use `event.stopImmediatePropagation`
- To prevent the browser's default action, call the method `event.preventDefault`

## Class Activity

[lectures/lecture-5/prop.html](#)  
[lectures/lecture-5/prop.js](#)

- Consider the JS sample code in **prop.js**. In what order are the messages in the event handler functions displayed?
- If you wanted to stop the event propagation in the bubble phase beyond `div3`, how will you do it?

# DOM Event Handling

1. Modern Browsers
2. DOM Event Handling
3. DOM Event Propagation
